

Analysis of Factors Affecting Movie Ratings

Alim Ata Balci – 32218

This project focuses on analyzing movie ratings using data science techniques. Movie ratings are influenced by various factors such as genre, release year, and audience preferences. In this project, I aim to analyze the factors that affect movie ratings using Netflix and IMDB datasets.

The data will be collected from publicly available datasets on Kaggle. The Netflix dataset will provide information such as movie titles, genres, release years, and durations, while the IMDB dataset will include ratings and vote counts. The data will be obtained by downloading CSV files.

The dataset is expected to include thousands of movies and will contain variables such as genre, release year, duration, rating, and number of votes.

To enrich the dataset, I will merge the Netflix dataset with IMDB data based on movie titles. This will allow me to combine content-related features with audience feedback and perform a more comprehensive analysis.

The goal of this project is to understand which features influence movie ratings and to build a simple machine learning model to predict ratings based on these features.
